

Use Case 1

Wire Instruction Extraction · Return on investment · October 2026

A day's 20 wire documents, processed in 1 minute instead of 20, with every routing and account number read correctly in testing.

20× faster than processing by hand	20 → 1 min to process 20 wire documents	100% routing and account numbers read correctly in testing	79 h staff hours returned per year at 20 documents a day
---	--	--	--

Time to process 20 wire documents

Figure 1. 20 documents at about 1 minute each by hand, against 20 documents a minute for the system.

Each wire transaction comes with a wire instruction document. Today a person reads each one and keys the beneficiary, bank, routing number and account number. The system reads the document, fills in those details and highlights any field that needs a closer look, so the time a person spends goes to checking rather than typing.

Accuracy

Fields read correctly, 100 test documents

Routing number (ABA)		100% 100 of 100
Account number		100% 100 of 100
Bank name		100% 100 of 100
Bank address		100% 100 of 100
Beneficiary name		83% 83 of 100
Beneficiary address		100% 100 of 100
Wrong values flagged for the reviewer		100% 17 of 17

Figure 2. Below 100%: Beneficiary name, 83 of 100. Every beneficiary name miss came from one layout whose page text spelled "&" as "&"; which was copied into the name. The software now converts it back before extraction; not yet re-tested. 83 of 100 documents had all six fields right.

Every value the system got wrong was flagged for a person to check. Mistral Document AI turns each page into text and gpt-6-luna extracts the fields from that text. Mistral's own reading of the page serves as a check: a field is

flagged when the two disagree, when its confidence is low, or, for routing numbers, when the ABA check digit fails. On average 0.9 of the six fields are flagged per document.

Value grows with volume

At 20 documents a day the system returns about 79 staff hours a year, worth \$3k after running costs. Most of the running cost is hosting, which stays the same as volume rises, so the value grows faster than the volume does.

Documents	By hand	Our system	Hours returned / year	Net value / year
10 a day	10 min	0.5 min	40 h	\$368
20 a day	20 min	1 min	79 h	\$3k
40 a day	40 min	2 min	158 h	\$7k
80 a day	80 min	4 min	317 h	\$16k
160 a day	160 min	8 min	633 h	\$33k

Annual value at 20 documents a day

Documents per year (20 a day, 250 working days)	5,000
Staff hours returned per year	79
Value of staff time at \$55/hour	\$4,400
Running cost (AI processing and hosting)	\$1,800
Net value per year	\$2,500

The build cost is not set yet. The table shows how much this use case could cost to build and still pay for itself at 20 documents a day.

To pay for itself within	6 months	12 months	24 months
The build can cost up to	\$1k	\$3k	\$5k

Running cost

AI processing per document	\$0.0038
AI processing per year at 20 documents a day	about \$19
Azure hosting, storage and monitoring per year	about \$1,800

Azure list prices: Mistral Document AI \$3.00 per 1,000 pages; gpt-6-luna \$0.10 and \$0.50 per million input and output tokens. Hosting is an estimate.

How it was tested

The wire step was tested on six synthetic wire instruction layouts chosen to be hard to read: repeated digits, small type in dense tables, fax-quality scans and details on a second page, all scanned to images. 18 live readings of those layouts were run 100 times through the production software, which scores every value and decides what to flag. A character misread when the page is turned into text would pass the other checks; the check digit catches that for routing numbers, and for the other fields the reviewer's comparison with the document remains the control.

Basis of the figures

- **Provided by the business:** about 20 wire documents a day; 20 minutes for a person to process them; 1 minute for the system.
- **Measured:** accuracy and flagging, as described under Accuracy.
- **Estimated:** 250 working days a year, a loaded staff cost of \$55 an hour, and hosting cost.
- **Not included:** time spent checking highlighted fields, the cost of building the system, and the avoided cost of a misdirected wire. Staff hours returned are capacity for other work, not a budget reduction unless roles change.
